A constraint-stabilized time-stepping approach for piecewise smooth multibody dynamics

Gary D. Hart
Department of Mathematics
University of Pittsburgh

April 4, 2007
Application of Rigid Multi Body Dynamics

- RMBD in diverse areas
  - rock dynamics
  - robotic simulations
  - virtual reality
  - human motion
  - nuclear reactors
  - haptics

- VR or Virtual reality exposure (VRE) therapy
  - fear of heights
  - telerehabilitation
  - fear of public speaking
  - PTSD
Some Previous Approaches

- **Integrate-detect-restart** simulation a natural choice
  - Classical solution may not exist
  - Collisions can cause small stepsizes

- **Differential algebraic equations (DAE)** for joint constraints
  - Specialized techniques because non-smooth noninterpenetration and friction constraints.

- **Optimization based animation** technique solving a quadratic program at each step to avoid stiffness.
  - Collision detection still present, hence small stepsizes

- **Penalty Barrier Methods** are most popular.
  - Easy set up, even for DAEs, but problem may be stiff and requires *a priori* smoothing parameters
Advantage:
- Results are same order of magnitude as penalty method
- Same dynamics using 4 orders of magnitude larger time step
- We use a velocity impulse LCP based approach avoiding the lack of a solution and introducing artificial stiffness

Disadvantage:
- LCP model yields inequality constraints from contact and friction, treated computationally as hard constraints.
Previous Approaches

Need to Define and Compute Depth of Penetration

- To avoid infinitely small time steps, say from collisions, then minimum stepsize must exist.

- For methods with minimum time step, interpenetration may be unavoidable, thus it needs to be quantified (to limit amount of interpenetration).

- Minimum Euclidean distance good for distance between objects, but not for penetration.

- Note that for convex polyhedra, calculation of PD using Minkowski sums, are computationally expensive.
Previous Approaches

Constraint Stabilization

- Constraint stabilization in a complementarity setting. Tackled by previous authors using
  - nonlinear complementarity problems an LCP
  - nonlinear projection (nonlinear inequality constraints)
  - post-processing method (uses potentially non-convex LCP)
  - convex LCP for constraint stabilization.

- Unlike ours, these methods need computation after solving basic LCP subproblem to achieve constraint stabilization.
The goals of this thesis are to

- define a new *computationally efficient* measure that detects collision and computes penetration of two convex bodies, which is metrically equivalent to the signed Euclidean distance when close to a contact,

- develop an algorithm which *efficiently* models the system and solves the resulting LCP while *achieving constraint stabilization*, and

- implement the algorithm to simulate polyhedral multibody contact problems with friction.
A constraint-stabilized time-stepping approach for piecewise smooth multibody dynamics

- Numerical Results
- Accomplishments
## Ratio Metric

- **We need a new measure** that defines distance and quantifies depth of penetration between convex bodies.

- We start by introducing and analyzing a new measure between two convex bodies.

- Then we extend the analysis to produce our new measure of penetration depth.

- **We will see that it is metrically equivalent to the Minkowski Penetration Depth measure, but has lower computational complexity.**
We define $CP(A, b, x_o)$ to be the convex polyhedron $P$ defined by the linear inequalities $Ax \leq b$ with an interior point $x_o$. We will often just write $P = CP(A, b, x_o)$.

Let $P = CP(A, b, x_o)$. Then for any nonnegative real number $t$, the expansion (contraction) of $P$ with respect to the point $x_o$ is defined to be

$$P(x_o, t) = \{ x | Ax \leq tb + (1 - t)Ax_o \}$$

and has an associated mapping

$$\Gamma(x, x_o, t) = tx + (1 - t)x_o.$$
Let $P_i = CP(A_i, b_i, x_i)$ be a convex polyhedron for $i = 1,2$. The Minkowski Penetration Depth (MPD) between the two bodies $P_1$ and $P_2$ is defined formally as

$$PD(P_1, P_2) = \min\{||d|| \mid \text{interior}(P_1 + d) \cap P_2 = \emptyset\}. \quad (1)$$
Definition

Let $P_i = CP(A_i, b_i, x_i)$ be a convex polyhedron for $i = 1,2$. The Minkowski Penetration Depth (MPD) between the two bodies $P_1$ and $P_2$ is defined formally as

$$PD(P_1, P_2) = \min\{||d|| \mid \text{interior}(P_1 + d) \cap P_2 = \emptyset\}. \quad (1)$$
Let $P_i = CP(A_i, b_i, x_i)$ be a convex polyhedron for $i = 1, 2$. Then the **Ratio Metric** between the two sets is given by

$$r(P_1, P_2) = \min \{ t | P_1(x_1, t) \cap P_2(x_2, t) \neq \emptyset \}, \quad (2)$$

and the corresponding **Ratio Metric Penetration Depth (RPD)** is given by

$$\rho(P_1, P_2, r) = \frac{r(P_1, P_2) - 1}{r(P_1, P_2)}. \quad (3)$$
Expansion/Contraction Again

**Figure:** Visual representation of double expansion or contraction
Metric Equivalence Theorem

Theorem (Metric Equivalence)

Let \( P_i = \text{CP}(A_i, b_i, x_i) \) be a convex polyhedron for \( i = 1, 2 \), \( s \) be the MPD between the two bodies, \( D \) be the distance between \( x_1 \) and \( x_2 \), \( \epsilon \) be the maximum allowable Minkowski penetration between any two bodies. Then the ratio metric penetration depth between the two sets satisfies the relationship

\[
\frac{s}{D} \leq \rho(P_1, P_2, r) \leq \frac{s}{\epsilon},
\]

if \( P_1 \) and \( P_2 \) have disjoint interiors, and

\[
-\frac{s}{\epsilon} \leq \rho(P_1, P_2, r) \leq -\frac{s}{D}
\]

if the interiors of \( P_1 \) and \( P_2 \) are not disjoint.
Significance of the Metric Equivalence Theorem

Let number of facets of two polyhedra be $m_1$ and $m_2$

- Computing PD by using the Minkowski sums: $O(m_1^2 + m_2^2)$
- Fast approximation to PD with stochastic method: $O(m_1^{3/4+\epsilon} m_2^{3/4+\epsilon})$ for any $\epsilon > 0$
- Solving linear programming problem: $O(m_1 + m_2)$

∴ our metric provide us with a simple way to detect collision and measure penetration of two convex polyhedral bodies with lower complexity and is equivalent, for small penetration, to the classical measure

∴ for time step $h$, if the MPD is $O(h^2)$ then so is the RPD

Perfect Contact

Definition

Two convex polyhedra are in perfect contact when there is a nonempty intersection without interpenetration.
Perfect Contact

Definition

Two convex polyhedra are in **perfect contact** when there is a nonempty intersection without interpenetration.

Definition

In n-dimensional space, a **Basic Contact Unit (BCU)** occurs when

- two convex polyhedra are in perfect contact,
- the contact region attached to a BCU is a point, and
- exactly n+1 facets are involved at the contact.

The point where the contact occurs is called an **event point**, or more simply, an **event**.
Basic Contact Unit

- A CoF is always a BCU
- In 2D: CoF  
- In 3D: CoF, (nonparallel) EoE
- In n-dim space, there are exactly \( \left\lfloor \frac{n+1}{2} \right\rfloor \) distinct BCUs

Figure: Corner-on-Face

Figure: Edge-on-Edge

Figure: Face-on-Face
Theorem

The intersection of two convex polyhedra in perfect contact is the convex hull of the event points.
Theorem

The intersection of two convex polyhedra in perfect contact is the convex hull of the event points.

**Figure:** 2D Example: Contact Region Is Convex Hull of BCUs.
In Calculus, we learn when functions are not differentiable. Consider piecewise smooth distance function.

**Figure:** Nondifferentiability of Euclidean distance function
Suppose that we have \( P_{L_i} = CP(A_{L_i}, b_{L_i}, 0) \) as the local representation for a convex polyhedron for \( i = 1, 2 \). The transformation from local coordinates \( x_{L_i} \) to world coordinates \( x \) is given by

\[
x = x_i + R_i x_{L_i},
\]

which can be rewritten into the form

\[
x_{L_i} = R_i^T(x - x_i).
\]

Here the matrices \( R_1 \) and \( R_2 \) are rotation matrices.
If E is an event at perfect contact of convex polyhedra $P_1$ and $P_2$, then $P_E(x_i, t)$, the restrictions of $P_i(x_i, t)$ to E, is the convex body defined by the facets of $P(x_i, t)$ which involve E.

If E is an event at perfect contact of $P_1$ and $P_2$, then

$$r(P_E(x_1, t), P_E(x_2, t)) = \min_{t \geq 0} \left\{ \begin{array}{l} \hat{A}_{L_1} R_1^T x - \hat{b}_1 t \leq \hat{A}_{L_1} R_1^T x_1 \\ \hat{A}_{L_2} R_2^T x - \hat{b}_2 t \leq \hat{A}_{L_2} R_2^T x_2 \end{array} \right.$$  \hspace{1cm} (6)

where the sum of the rows of $\hat{A}_{L_1}$ and $\hat{A}_{L_2}$ totals $n+1$.

Theorem: At any event E of perfect contact, $r(P_E(x_1, t), P_E(x_2, t))$ is infinitely differentiable with respect to the translation vectors and rotation angles.
Component Functions

- Associate $m^{th}$ event $E^{(m)}$ with component function $\hat{\Phi}^{(m)}$
- We use the restrictions $P_{E^{(m)}}(x_1, t)$ and $P_{E^{(m)}}(x_2, t)$
- $\hat{\Phi}^{(m)} = f(r_m)$, where $f(t) = (t - 1)/t$ and

$$r_m = \min_{t \geq 0} \left\{ \begin{array}{l} \hat{A}_m R_1^T x - b_m t \leq \hat{A}_m R_1^T x_1 \\ \hat{A}_m R_2^T x - b_m t \leq \hat{A}_m R_2^T x_2 \end{array} \right\} \quad (7)$$

and sum of numbers of rows of $\hat{A}_m$ and $\hat{A}_m$ is $n+1$.

**Figure:** Uniqueness and Two Component Signed Distance Functions
Differentiability at an Event

Max of Component Functions

RPD is the maximum of component distance functions.

**Theorem**

Suppose \( x_1 \neq x_2 \) and let \( P_i = CP(A_{L_i} R_i^T, b_{L_i} + A_{L_i} R_i^T x_i, x_i) \) be convex polyhedra for \( i = 1, 2 \) and let \( \{E(1), E(2), \ldots, E(N)\} \) be the list of all possible events with corresponding component distance functions \( \{\hat{\phi}(1), \hat{\phi}(2), \ldots, \hat{\phi}(N)\} \). Then

\[
\rho(P_1, P_2, r) = \max \left\{ \hat{\phi}(1), \hat{\phi}(2), \ldots, \hat{\phi}(N) \right\},
\]

where \( \rho(P_1, P_2, r) \) is defined by (3).

Physical Constraints

Polyhedral Bodies

- For the $j_i^{th}$ body, we define $P_{ji} = CP(A_{ji}, b_{ji}, 0)$ to be the polyhedron defined by the linear inequalities

$$A_{ji}x \leq b_{ji}$$

which contains the origin.

- Normalize this system such that all entries of vector $b_{ji}$ are equal to 1.

- This approach is very relevant and more robust since any body can be approximated using convex polyhedra, the prevalent representation in computer graphics.
Model noninterpenetration constraints by continuous piecewise differentiable signed distance functions:

\[ \Phi^{(j)}(q) \geq 0, \quad j = 1, 2, \ldots, p. \]  

We will use RPD to compute \( \Phi^{(j)} \)

**Figure:** Noninterpenetration Constraint: Constraint not enforced
Joint Constraints

- Model joint constraints by sufficiently smooth 
  \[ \Theta^{(i)}(q) = 0, \quad i = 1, 2, \ldots, n_J \]
- Define \( \nu^{(i)}(q) = \nabla_q \Theta^{(i)}(q), \quad i = 1, 2, \ldots, n_J \)
Physical Constraints

Joint Constraints

- Model joint constraints by sufficiently smooth \( \Theta^{(i)}(q) = 0, \ i = 1, 2, \cdots, n_J \)
- Define \( \nu^{(i)}(q) = \nabla_q \Theta^{(i)}(q), \ i = 1, 2, \cdots, n_J \)

Figure: Joint Constraint: Fixed distance between wheels
For two bodies in contact at position $q$, $\Phi(j)(q) = \Phi_k(j)(q) = 0$ and hence $\hat{\Phi}(m)(q) = 0$ for some $m$, $1 \leq m \leq p_o$.

Include set of *imminently active events* in dynamical resolution. Determine Set $\mathcal{E}$ by choosing parameters $\hat{\epsilon}_t$ and $\hat{\epsilon}_x$:

\[
\mathcal{E}_1(q) = \left\{ m \mid \Phi(j) \leq \hat{\epsilon}_t, j = \text{Bod}(E^{(m)}) \right\} \\
\mathcal{E}_2(q) = \left\{ m \mid 0 \leq \hat{\Phi}(m) - \Phi(j) \leq \hat{\epsilon}_t, j = \text{Bod}(E^{(m)}) \right\} \\
\mathcal{E}_3(q) = \left\{ m \mid E_x^{(m)} \in CP(A_{Lm_1}R_{m_2}^T, b_{Lm_1} + A_{Lm_1}R_{m_1}^T x_{m_1}, x_{m_1}) + \hat{\epsilon}_x \right\} \\
\mathcal{E}_4(q) = \left\{ m \mid E_x^{(m)} \in CP(A_{Lm_2}R_{m_2}^T, b_{Lm_2} + A_{Lm_2}R_{m_2}^T x_{m_2}, x_{m_2}) + \hat{\epsilon}_x \right\}
\]

and

\[
\mathcal{E}(q) = \mathcal{E}_1(q) \cap \mathcal{E}_2(q) \cap \mathcal{E}_3(q) \cap \mathcal{E}_4(q).
\]
Define \textit{computationally active set} (or nearly active set) by

\[ A(q) = \left\{ j \mid \Phi^{(j)}(q) \leq \epsilon_t, j = 1, \cdots, p \right\}, \quad (11) \]

where \( \epsilon_t > 0 \) is a given parameter.

For a given position \( q \), then \( A(q) = \emptyset \iff \mathcal{E}(q) = \emptyset \)
Contact Model

- Normal at an event \((m)\): \(n^{(m)}(q) = \nabla_q \Phi^{(m)}(q), \quad m \in \mathcal{E}\)
- If one BCU per contact, complementarity of contact and compression impulse: \(\hat{\Phi}^{(m)}(q) \geq 0 \perp c_n^{(m)} \geq 0, \quad m \in \mathcal{E}\)
Contact Model

- Normal at an event \( (m) : n^{(m)}(q) = \nabla_q \Phi^{(m)}(q), \quad m \in \mathcal{E} \)
- If one BCU per contact, complementarity of contact and compression impulse: \( \Phi^{(m)}(q) \geq 0 \perp c_n^{(m)} \geq 0, \quad m \in \mathcal{E} \)

**Figure:** Contact Model in the case of one BCU per contact
Euler discretization of the equations of motion:

\[
M(q^{(l)}) (\mathbf{v}^{(l+1)} - \mathbf{v}^{(l)}) = h_l k (t^{(l)}, q^{(l)}, \mathbf{v}^{(l)}) + \sum_{i=1}^{n_J} c_{\nu}^{(i)} \nu^{(i)}(q^{(l)}) + \sum_{m \in \mathcal{E}} \left( c_{n}^{(m)} n^{(m)}(q^{(l)}) + \sum_{i=1}^{M_{\mathcal{C}}} \beta_{i}^{(m)} d_{i}^{(m)}(q^{(l)}) \right)
\]

(12)

Modified linearization of geometrical and noninterpenetration constraints:

\[
\gamma \Theta^{(i)}(q^{(l)}) + h_l \nu^{(i)T}(q^{(l)}) \mathbf{v}^{(l+1)} = 0, \quad i = 1, 2, \ldots, n_J,
\]

\[
n^{(m)T}(q^{(l)}) \mathbf{v}^{(l+1)} + \frac{\gamma}{h_l} \Phi^{(j)}(q^{(l)}) \geq 0 \quad \perp c_{n}^{(m)} \geq 0, \quad m \in \mathcal{E}.
\]

(13)
Friction model (usual classical pyramid approximation of friction cone, see Stewart & Trinkle 1995 or Anitescu & Hart 2004):

\[
\begin{align*}
D^{(m)}(q) v + \lambda^{(m)} e^{(m)} & \geq 0 \perp \beta^{(m)} \geq 0, \\
\mu c^{(m)} - e^{(m)T} \beta^{(m)} & \geq 0 \perp \lambda^{(m)} \geq 0.
\end{align*}
\]

(14)
Mixed Complementarity and QP Formulation

\begin{align*}
M^{(l)} v & - \tilde{n} \tilde{c}_n - \tilde{D} \tilde{\beta} = -q^{(l)} \\
\tilde{\nu}^T v & = -\gamma \\
\tilde{n}^T v & - \tilde{\mu} \lambda \geq -\Gamma - \Delta \quad \perp c_n \geq 0 \\
\tilde{D}^T v & + \tilde{E} \lambda \geq 0 \quad \perp \tilde{\beta} \geq 0 \\
\tilde{\mu} c_n & - \tilde{E}^T \tilde{\beta} \geq 0 \quad \perp \lambda \geq 0
\end{align*}
Mixed Complementarity and QP Formulation

\[
\begin{align*}
M^{(l)} v - \bar{n} \bar{c}_n - \bar{D} \bar{\beta} &= -q^{(l)} \\
\bar{v}^T v &= -\gamma \\
\bar{n}^T v &\geq -\Gamma - \Delta \quad \bot \quad c_n \geq 0 \\
\bar{D}^T v &\geq 0 \quad \bot \quad \bar{\beta} \geq 0 \\
\bar{\mu} c_n - \bar{E}^T \bar{\beta} &\geq 0 \quad \bot \quad \lambda \geq 0
\end{align*}
\]

Note (15) constitutes 1\textsuperscript{st}-order optimality conditions of QP

\[
\begin{align*}
\min_{v, \lambda} \frac{1}{2} v^T M^{(l)} v + q^{(l)^T} v \\
\text{s.t.} \quad n^{(m)^T} v - \mu^{(m)} \lambda^{(m)} &\geq -\Gamma^{(m)} - \Delta^{(m)} , \quad m \in \mathcal{E} \\
D^{(m)^T} v + \lambda^{(m)} e^{(m)} &\geq 0 , \quad m \in \mathcal{E} \\
\nu_i^T v &= -\gamma_i , \quad 1 \leq i \leq n_J \\
\lambda^{(m)} &\geq 0 \quad m \in \mathcal{E}
\end{align*}
\]

**Algorithm for Nearly Active Events**

**Algorithm**

**Step 1:** Solve the dual problem.

**Step 2:** List the active hyperplanes $H_{1i}$, $i = 1, \ldots, n_1$ and $H_{2j}$, $j = 1, \ldots, n_2$.

**Step 3:** Choose appropriate parameter $\epsilon$.

**Step 4a:** Check $H_{1i}$ with the list of $\epsilon$ adjacent points of $H_{2j}$.

**Step 4b:** Check $H_{2j}$ with the list of $\epsilon$ adjacent points of $H_{1i}$.

**Step 4c:** Check $\epsilon$ adjacent edges of $H_{1i}$ and $H_{2j}$.

Because we do not stop nor reduce time steps, we need to include events that would be active at the next step, thus we use “nearly active” events.

Infeasibility

Definition of Measure of Infeasibility

- Set of allowable positions for some $\epsilon > 0$, the sets
  - $\Omega_{\epsilon}^\Phi = \{ q \in Q | \Phi(j)(q) \geq -\epsilon, 1 \leq m \leq p \}$
  - $\Omega_{\epsilon}^\Theta = \{ q \in Q | |\Theta(i)(q)| \geq -\epsilon, i = 1, 2, \ldots, n_J \}$
  - $\Omega_{\epsilon} = \Omega_{\epsilon}^\Phi \cap \Omega_{\epsilon}^\Theta$

- Measure of infeasibility
  $$\text{I}(q) = \max_{1 \leq j \leq p, 1 \leq i \leq n_J} \left\{ \Phi(j)(q), |\Theta(i)(q)| \right\}$$
Assumption A1

A1: There exists $\epsilon_o > 0$, $C_1^d > 0$, and $C_2^d > 0$ such that

- $\Phi(j)$ for $1 \leq j \leq n_B$ are piecewise continuous on their domains $\Omega_\epsilon$, with piecewise components $\hat{\Phi}(m)(q)$ which are twice continuously differentiable in their respective open domains with first and second derivatives uniformly bounded by $C_1^d > 0$ and $C_2^d > 0$, respectively, and

- $\Theta(i)(q)$ for $i = 1, 2, \cdots, m$ are twice continuously differentiable in $\Omega_\epsilon$ with first and second derivatives uniformly bounded by $C_1^d > 0$ and $C_2^d > 0$, respectively.
Using Assumption A1

**Lemma**

If Assumption A1 holds, then \( \Phi(j) \) for \( 1 \leq j \leq n_B \) is everywhere directionally differentiable. Moreover, the generalized gradient of \( \Phi(j) \) is contained in the convex cover of the gradients of its component functions which are active at \( q \) evaluated at \( q \).

Note: We use \( \Phi^{(j)}(q; v) = \limsup_{p \to q, t \downarrow 0} \frac{\Phi(j)(p + tv) - \Phi(j)(p)}{t} \)

Assumptions

Using Assumption A1

Lemma

If Assumption A1 holds, then $\phi^{(j)}$ for $1 \leq j \leq n_B$ is everywhere directionally differentiable. Moreover, the generalized gradient of $\phi^{(j)}$ is contained in the convex cover of the gradients of its component functions which are active at $q$ evaluated at $q$.

Note: We use $\phi^{(j)}(p; v) = \limsup_{p \to q, t \downarrow 0} \frac{\phi^{(j)}(p + tv) - \phi^{(j)}(p)}{t}$

Lemma

If Assumption A1 holds, then for any $j$ such that $1 \leq j \leq n_B$, then $\phi^{(j)}$ satisfies a Lipschitz condition.

Note: We use Lebourg’s Mean Value Theorem in the proof.
Assumptions D1 - D3

**D1:** The mass matrix is constant. That is, $M(q^{(l)}) = M^{(l)} = M$.

**D2:** The norm growth parameter is constant: $c(\cdot, \cdot, \cdot) \leq c_o$

**D3:** The external force is continuous and increases at most linearly with the pos. and vel., and unif. bdd in time:

$$k(t, v, q) = k_o(t, v, q) + f_c(v, q) + k_1(v) + k_2(q)$$

and there is some constant $c_K \geq 0$ such that

$$\|k_o(t, v, q)\| \leq c_K$$
$$\|k_1(v)\| \leq c_K \|v\|$$
$$\|k_2(q)\| \leq c_K \|q\|.$$

Also assume

$$v^T f_c(v, q) = 0 \quad \forall v, q.$$
Main Algorithm

Algorithm for Piecewise Smooth RMBD

Algorithm for piecewise smooth multibody dynamics

**Step 1:** Given $q^{(l)}$, $\nu^{(l)}$, and $h_l$, calculate the active set $\mathcal{A}(q^{(l)})$ and active events $\mathcal{E}(q^{(l)})$.

**Step 2:** Compute $\nu^{(l+1)}$, the velocity solution of our mixed LCP.

**Step 3:** Compute $q^{(l+1)} = q^{(l)} + h_l \nu^{(l+1)}$.

**Step 4:** IF finished, THEN stop ELSE set $l = l + 1$ and restart.
Consider the time-stepping algorithm defined above and applied over a finite time interval [0, $T$]. Assume that

- The active set $\mathcal{A}(q)$ is defined by (11)
- The active events $\mathcal{E}(q)$ are defined by (10)
- The time steps $h_l > 0$ satisfy
  \[ \sum_{l=0}^{N-1} h_l = T \quad \text{and} \quad \frac{h_{l-1}}{h_l} = c_h, \quad l = 1, 2, \cdots, N - 1 \]
- The system satisfies Assumptions (A1) and (D1) - (D3)
- The system is initially feasible. That is, $I(q^{(0)}) = 0$

Then, there exist $H > 0$, $V > 0$, and $C_{c} > 0$ such that

\[ \|v^{(l)}\| \leq V \quad \text{and} \quad I(q(l)) \leq C_{c} \|v^{(l)}\|^2 h_{l-1}^2, \quad \forall l, \quad 1 \leq l \leq N \]
Proof that Algorithm works

From of Proof

- Proof proceeds similarly to proof in Anitescu & Hart 2004 and used a Theorem in the same paper.

- We use Lebourg’s Mean Value Theorem which states that given $q_1$ and $q_2$ in the domain of $\Phi^{(j)}$, there exists $q_o$ on the line segment between $q_1$ and $q_2$ that satisfies

$$\Phi^{(j)}(q_1) - \Phi^{(j)}(q_2) \in \left< \partial \Phi^{(j)}(q_o), q_1 - q_2 \right>.$$ 

This means that there is some $\Gamma \in \partial \Phi^{(j)}$ such that

$$\Phi^{(j)}(q_1) - \Phi^{(j)}(q_2) = \Gamma(q_1 - q_2).$$

Here $\partial \Phi^{(j)}$ is the generalized gradient.
Algorithm achieves constraint stabilization because the infeasibility is bounded above by the size of the solution. In particular, $v^{(l+1)} = 0 \Rightarrow l(q^{(l+1)}) = 0$

- Linear $O(h)$ method yields quadratic $O(h^2)$ infeasibility
- Velocity remains bounded
- No need to change the step size to control infeasibility
- Solve one linear complementarity problem per step

Accomplishments from This Thesis

- Successfully developed a computationally efficient signed distance function, Ratio Metric
- Successfully shown equivalence of RPM to MPD
- Successfully calculated generalized gradients and showed that infeasibility at step \( l \) is upper bounded by
  \[
  O\left( \| h_{l-1} \|^2 \| \nu^{(l)} \|^2 \right)
  \]
- Successfully developed and analyzed algorithm that achieves constraint stabilization solving one LCP per step
- Successfully implemented this algorithm for several problems with good results
List of Publications

- Publications in preparation: One dealing with Depth of Penetration by Linear Programming, the other dealing with Constraint Stabilization for Nonsmooth Shapes.
Future Research

- I plan to demonstrate that computation of RPD is faster than computation of MPD

- I plan to optimize the algorithm. For example, I need to find a rigorous way to reduce the number of active gradients

- I plan to evaluate the bounds of constraint stabilization, because it would be interesting to explore the possibility of constraint stabilization results being useful for values of $\gamma \geq 1$

- I plan to increase the library of successfully solved examples, including the famous Brazil Nut problem
Research Accomplishments

Thank You! Thank You! Thank You! Thank You! Thank You! Thank You!
